[Abstract] **Objective** To observe the prevention and control effect of 1% atropine on the progression of form deprivation myopia (FDM) in guinea pigs and the potential biological mechanism. **Methods** Sixty-nine 3-week-old tricolor guinea pigs with normal refraction were randomly divided into a normal control group ($n=19$), a FDM group ($n=19$), a FDM+atropine group ($n=19$), and an atropine group ($n=12$). No intervention was given to guinea pigs in normal control group. The FDM model was established by covering the right eye of guinea pigs with a semitransparent latex facemask for 4 weeks in FDM and FDM+atropine groups. For the FDM+atropine group, 1% atropine gel was topically administered to the form-deprived right eyes once a day for 4 weeks. For the atropine group, the right eye was treated with 1% atropine gel once a day for 4 weeks. Refraction and axial length of guinea pigs were measured by retinoscopy and ophthalmic A-scan ultrasonography respectively at baseline, experiment week 2 and week 4. In experiment week 4, eyeballs were enucleated to make sections via the paraffin wax processing procedure, and the microstructural and ultrastructural changes of the sclera were observed under the light microscope and transmission electron microscope, respectively. The isobaric tags for relative and absolute quantitation labeling combined with liquid chromatography-tandem mass spectrometry were used to identify the differentially expressed proteins. Use and care of the animals complied with the Regulation for the Administration of Affairs Concerning Experiment Animals by State Science and Technology Commission. The study protocol was approved by the Institutional Animal Care and Use Committee of Tianjin Medical University (No. TJYY2020111028). **Results** There were statistically significant differences in the diopter of guinea pigs at different time points among the four groups ($F_{group} = 138.892, P < 0.001$; $F_{time} = 167.270, P < 0.001$). Compared with normal control group, the diopter of guinea pigs in FDM group at experiment weeks 2 and 4, and FDM + atropine group at experiment week 4 developed toward myopia, showing statistically significant differences (all at $P < 0.001$). Compared with FDM group, the diopter of guinea pigs in FDM+atropine group at experiment weeks 2 and 4 developed toward hyperopia, showing statistically significant differences (both at $P < 0.001$). There were statistically significant differences in the axial length of guinea pigs at different time points among the four groups ($F_{group} = 32.346, P < 0.001$; $F_{time} = 353.797, P < 0.001$). The axial lengths of FDM group at experiment weeks 2 and 4 and FDM+atropine group at experiment week 4 were longer than those of normal control group, and the axial lengths in FDM+atropine group at experiment weeks 2 and 4 were shorter than those in FDM group, and the differences were statistically significant (all at $P < 0.001$). The collagenous fibers of posterior sclera of guinea pigs were loose and disordered in FDM group, and were regular in FDM+atropine group. The posterior scleral thickness of normal control group, FDM group, FDM + atropine group and atropine group was (141.74±16.98), (101.46±9.15), (112.74±6.24) and (134.30±18.19) μm, respectively, with a statistically significant difference ($F = 6.709, P = 0.005$). The posterior sclera was significantly thinner in FDM group than in normal control group and FDM+atropine group (both at $P < 0.05$). The diameter of posterior scleral collagen fiber gradually increased from inside to outside in normal control group, FDM+atropine group and atropine group, and the diameters of the inner, middle and outer posterior scleral collagen fibers were smaller in FDM group than in normal control group. Proteomic analysis revealed 85 differentially expressed proteins (fold change > 1.30) between FDM group and normal control group, FDM+atropine group and FDM group, of which 38 were up-regulated and 47 were down-regulated after atropine treatment. Gene Ontology enrichment analysis showed that biological processes mainly involved were biological regulation, cell process, localization and metabolic process. Molecular function mainly involved were binding, catalytic activity, molecular function regulator, structural molecule activity and transporter activity. Cell components mainly involved were in cellular anatomical entity, intracellular and protein-containing complex. **Conclusions** Atropine can increase the diameter of scleral collagen fibers in guinea pigs of FDM model, improve the arrangement of scleral collagen fiber, inhibit scleral thinning. The mechanism of atropine to control myopia progression is closely related to the tight junction between scleral cells, cytoskeleton and extracellular matrix remodeling.

近视是视觉损害的主要原因之一,随着近视患病率的急剧升高,近视人群趋于低龄化^[1],尤其在新型冠状病毒感染疫情期间,中国儿童近视患病率明显升高,近视风险显著增加^[2],近视已成为我国重大公共卫生问题及社会问题。阿托品眼用制剂局部应用是目前临床用于控制近视的主要方法之一,多项研究已证实其对青少年近视进展控制和预防的有效性^[3-5]。一项 Meta 分析显示,相较于单光镜矫正,高浓度阿托品滴眼液长期点眼可使青少年近视进展量每年减少(0.68 ± 0.14)D,眼轴增长量每年减少(0.21 ± 0.22)mm^[6]。既往研究表明,巩膜变薄、胶原纤维排列紊乱、纤维直径变细、巩膜生物力学性能下降、眼轴增长是近视发生和发展的重要形态学改变^[7-10];而阿托品眼用制剂局部应用可防止近视眼巩膜的变薄,促进巩膜细胞外基质合成^[11-12];推测阿托品眼用制剂对近视进展和眼轴增长的抑制作用可能与巩膜组织重塑有关。然而,目前阿托品如何作用于巩膜组织及其潜在的生物学机制等问题尚未阐明。本研究拟观察质量分数 1% 阿托品对形觉剥夺性近视 (form deprivation myopia, FDM) 豚鼠巩膜组织形态及超微结构的影响,探讨阿托品对巩膜组织形态学改变及巩膜重塑的作用及潜在机制。

3 讨论

低浓度阿托品的应用是近年来近视防控研究的热点。Zhou 等^[13]及 Zou 等^[14]研究报道 1% 阿托品对豚鼠 FDM 屈光度的控制效果分别为 60.75% 和 76.92%，对眼轴长度的控制效果分别为 57.89% 和 50.00%。临床试验也已证实不同浓度阿托品对儿童及青少年近视进展有显著控制效果^[15]。Yam 等^[16]研究表明，0.05% 阿托品持续使用 1 年对近视屈光度及眼轴长度的控制效果分别可达 66.67% 和 51.22%。本实验用 1% 阿托品凝胶干预豚鼠 FDM 进展，结果表明其对近视屈光度及眼轴长度的控制效果分别为 52.90% 和 61.54%，与已有动物研究结果相似^[13-14]，证实阿托品可有效控制豚鼠 FDM 进展。

既往研究表明，近视眼轴伸长后，眼球后极部巩膜组织形态结构发生改变，Zi 等^[8]和 McBrien 等^[9]在光学显微镜下观察豚鼠和树鼩近视模型眼球形态，发现后极部巩膜明显变薄，胶原纤维分布稀疏、排列紊乱，透射电子显微镜下观察发现胶原纤维直径减小，纤维密度降低。McBrien 等^[9]对巩膜进一步分层观察，发现形觉剥夺时间较短的树鼩后极部巩膜内、中、外层胶原纤维直径未发生改变，形觉剥夺时间延长可使巩膜各层胶原纤维直径均减小，其中外层纤维直径改变最明显，与 Lin 等^[7]和 Funata 等^[17]在猴 FDM 模型及家兔离焦诱导性近视模型后极部巩膜内、中、外层胶原纤维中观察到的结果一致。本实验在光学显微镜下观察发现，FDM 豚鼠后极部巩膜组织变薄，胶原纤维排列疏松且紊乱，透射电子显微镜下可见胶原纤维直径变细，外层胶原纤维变化最明显，与既往研究结果一致。巩膜作为眼球的主要力学支撑架构，具有承受眼内压力，维持眼球形态的作用，而巩膜变薄、纤维变细会降低巩膜的机械强度，导致眼球在眼压作用下更容易扩张，眼轴伸长引发近视进展，而增强眼球后极部巩膜的

机械强度能够有效抑制眼轴的增长^[18-20]。因此，阿托品能否通过改善巩膜形态及超微结构防控近视值得关注。

Barathi 等^[11]在离焦诱导性近视模型小鼠结膜下注射 1% 阿托品，发现其后极部巩膜厚度为 $(70.5 \pm 0.05) \mu\text{m}$ ，较结膜下注射生理盐水的近视小鼠后极部巩膜厚度 $(53.9 \pm 0.05) \mu\text{m}$ 明显变厚，表明阿托品可抑制近视眼后极部巩膜变薄，但该研究未能从巩膜组织胶原纤维形态学及超微结构层面观察阿托品对巩膜组织的影响。本研究分别观察了正常对照组、FDM 模型组、FDM+阿托品组及阿托品组在光学显微镜及透射电子显微镜下后极部巩膜厚度及胶原纤维形态，结果显示相较于 FDM 模型组，FDM+阿托品组巩膜厚度增加，胶原纤维排列改善、直径增大，表明阿托品可增加近视豚鼠后极部巩膜组织厚度，改善胶原纤维形态及结构。

为进一步揭示阿托品对近视巩膜组织形态学改变的潜在作用机制，本实验通过蛋白质组学探讨阿托品对近视动物模型后极部巩膜组织蛋白的调控作用，结果显示差异蛋白主要有细胞外基质蛋白和细胞骨架蛋白。Hsiao 等^[21]利用下一代测序和生物信息学方法研究发现，阿托品控制眼轴增长的差异表达基因涉及改变细胞外基质结构的基因，推测阿托品对近视的调控作用可能与细胞外基质重塑密切相关。细胞外基质改变在巩膜生长、眼轴伸长中发挥重要作用^[22]。细胞外基质主要由胶原蛋白组成，本研究发现 I 型胶原蛋白 $\alpha 1$ (collagen type I $\alpha 1$ chain, COL1A1) 在 FDM 模型组中表达下调，在 FDM+阿托品组上调。已有研究表明，在近视发生和发展过程中，巩膜组织中 COL1A1 表达下调，京尼平和溴莫尼定的使用均可上调巩膜组织中 COL1A1 的表达，抑制近视的发生和发展^[23-25]，表明 COL1A1 是药物控制近视进展过程中的关键蛋白。因此，阿托品可能通过上调 COL1A1 的表达，增加胶原蛋白合成，改善胶原纤维排列，影响细胞外基质重塑，增强巩膜组织生物力学特性，抑制眼轴伸长。

胰岛素降解酶 (insulin degrading enzyme, IDE) 是一种非典型的锌金属内肽酶，可水解胰岛素和其他中等大小的肽激素，可优先降解结构相似的多肽，如 IDE 可降解胰岛素样生长因子 (insulin like growth factor, IGF)。本实验发现，IDE 在 FDM 模型组表达下调，在 FDM+阿托品组上调。已有研究表明 IGF 及其受体在形觉剥夺及离焦诱导性近视模型巩膜组织中表达增加^[26-28]。IGF 是一类具有促生长作用的多肽类物质，与其受体结合可使酪氨酸蛋白激酶活化 PI3K/Akt/

mTOR 信号通路, 调节成纤维细胞向肌成纤维细胞分化, 影响细胞外基质合成^[29]。已有研究表明, PI3K/AKT/mTOR 信号通路可能参与对病理性近视相关因子的调控^[30-31]。因此我们推测阿托品干预使巩膜组织中 IDE 表达增加, 可能通过调控 IGF 表达, 减少与 IGF 受体的结合, 影响 PI3K/AKT/mTOR 信号通路, 改善巩膜细胞外基质重塑, 进而发挥近视控制作用。

细胞骨架在维持细胞形态、承受外力、保持细胞内部结构的有序性方面起重要作用, 与结合蛋白组成动力系统可增强机械强度。Frost 等^[32] 和 Yuan 等^[33] 研究发现, 细胞骨架蛋白与近视发生和发展有关, 因此我们推测细胞骨架蛋白在近视发展及近视控制中均发挥重要作用。肌动蛋白结合 LIM 蛋白 1 (actin binding LIM protein 1, ABLIM1) 是细胞骨架肌动蛋白结合蛋白, 其在 FDM 模型组表达下调, 在 FDM+ 阿托品组表达上调。研究发现 ABLIM1 与肌动蛋白网络紧密连接相关, 其构成的肌动蛋白网络可抵消机械张力的作用, ABLIM1 缺失会破坏肌动蛋白的结构, 削弱对外界机械张力的抵抗^[34]。由此推测阿托品干预后 ABLIM1 的增加可能与增强巩膜细胞间紧密连接、增强巩膜组织的机械强度有关。因此阿托品可能通过改善细胞骨架, 进而影响胶原纤维形态及结构, 增加巩膜厚度, 控制眼轴伸长。

本研究富集通路分析发现, 差异蛋白主要与整合素信号通路、Rho GTP 酶对细胞骨架重组调控信号通路相关。Yuan 等^[33] 发现在豚鼠 FDM 模型中, 与近视相关的差异蛋白主要与整合素信号通路相关。近视进展过程中胶原结合整合素的表达水平下降, 整合素可作为潜在靶点以减缓近视诱导期间眼轴伸长^[35-37]。整合素作为细胞黏附分子, 可与细胞外基质蛋白和细胞骨架蛋白共同形成一个动态网络。当细胞受到外源性机械力时, 细胞黏附分子感知并传递机械刺激到细胞骨架, 进一步激活 RhoA 从 GDP 结合状态到 GTP 结合状态^[38-39], 诱导细胞骨架发生变化, 造成肌成纤维转分化^[40-42], 从而影响巩膜细胞外基质重塑。

综上所述, 本研究结果表明阿托品可改善巩膜胶原纤维排列, 增加后极部巩膜厚度, 影响巩膜重塑, 其对巩膜组织形态学的作用机制可能与细胞间紧密连接及细胞骨架蛋白密切相关。本实验仅探讨阿托品对近视巩膜组织形态学及蛋白质谱的影响, 阿托品如何作用于巩膜组织蛋白产生影响及蛋白如何发挥其对巩膜组织的调控作用仍需进一步研究。
